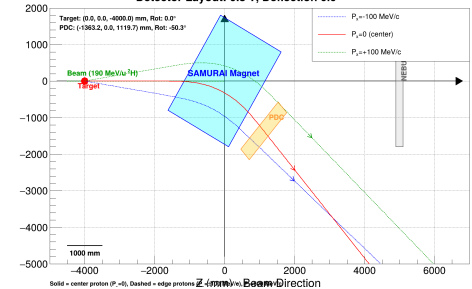
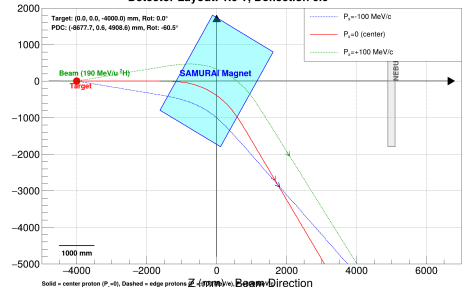
Rationale for Target Placement

Why the target must be placed inside the magnetic field:

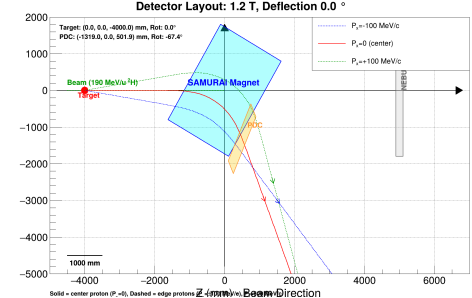
- **Strong B-field Case:**
  - Difficult proton track reconstruction.
- **Weak B-field Case:**
  - Risk of protons hitting the exit window.
- **General Constraint:**
  - Poor neutron geometric acceptance.



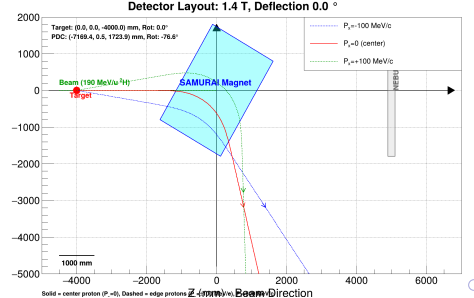
(a) 0.80 T



(b) 1.00 T

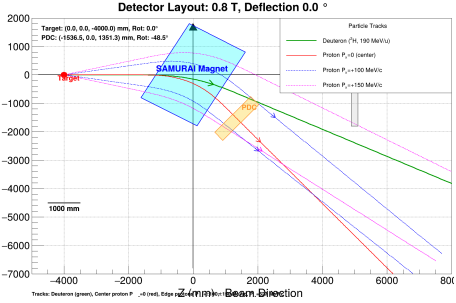


(c) 1.20 T

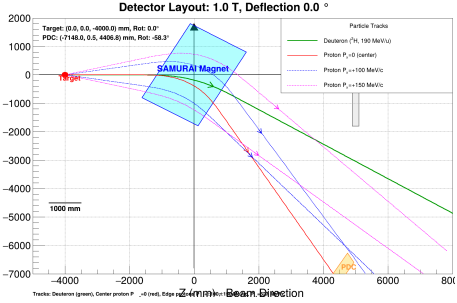


(d) 1.40 T

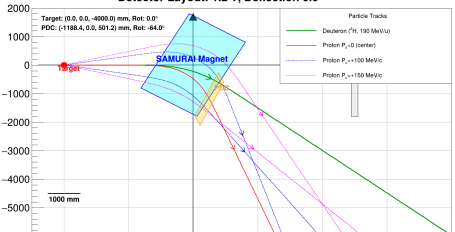
PDC Position: 0 deg (Low Field)



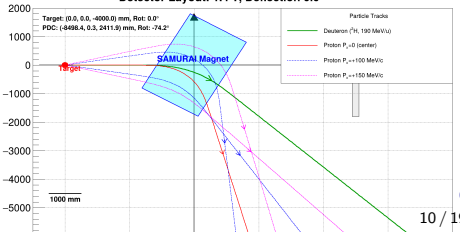
(a) 0.80 T



(b) 1.00 T

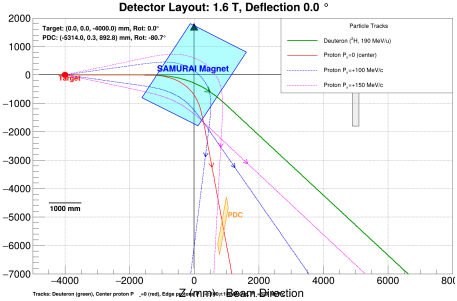


(c) 1.20 T

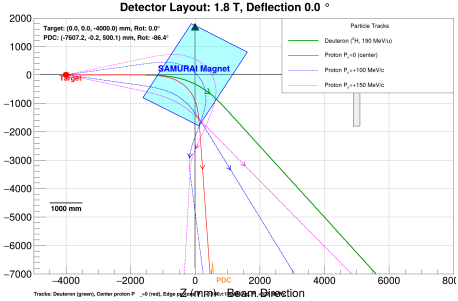


(d) 1.40 T

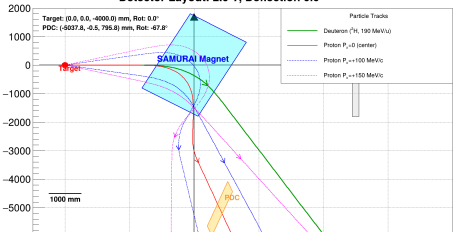
PDC Position: 0 deg (Mid Field)

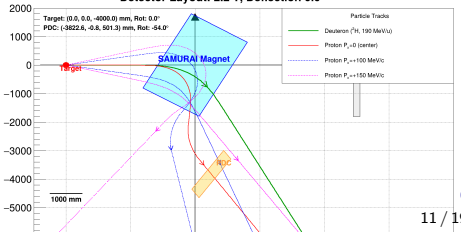


(a) 1.60 T

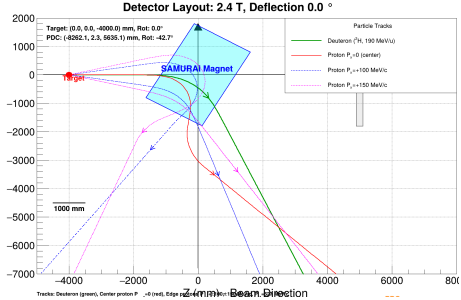


(b) 1.80 T

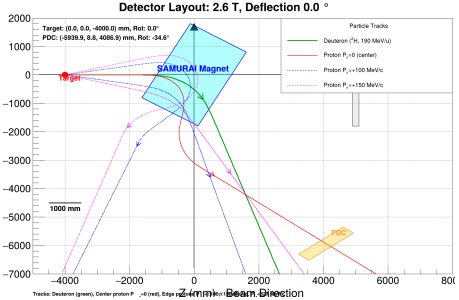




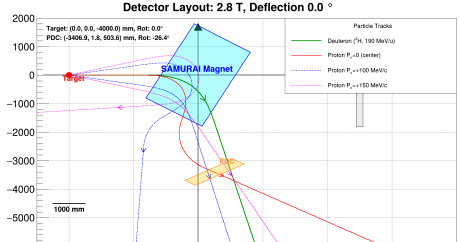
PDC Position: 0 deg (High Field)



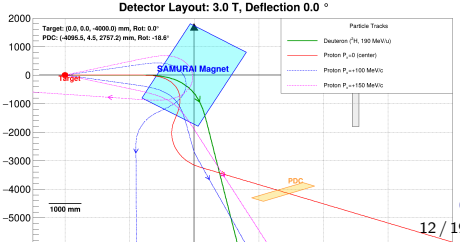
(a) 2.40 T



(b) 2.60 T

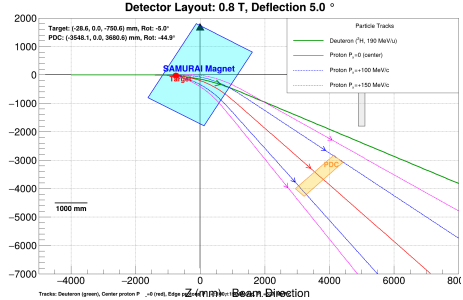


(c) 2.80 T

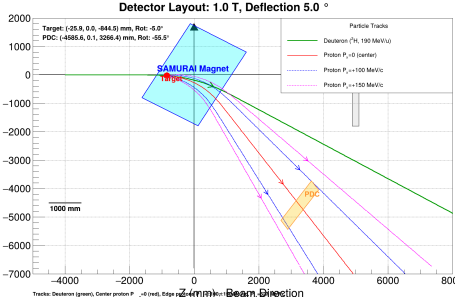


(d) 3.00 T

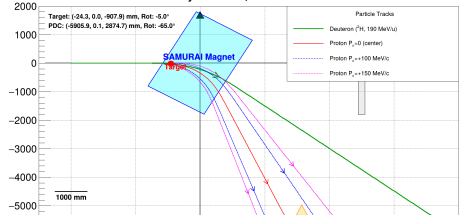
PDC Position: 5 deg (Low Field)

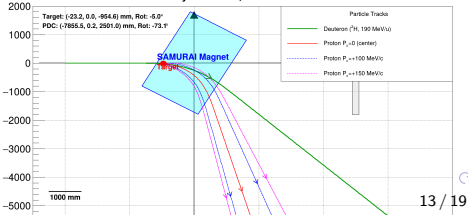


(a) 0.80 T

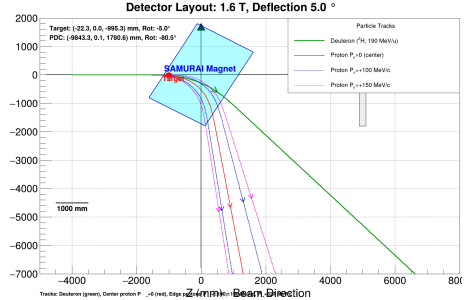


(b) 1.00 T

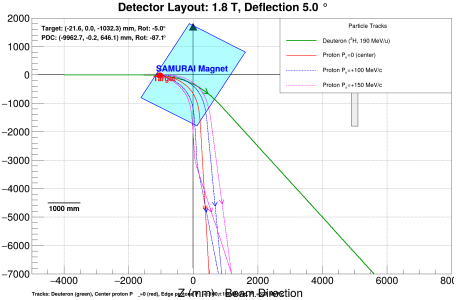




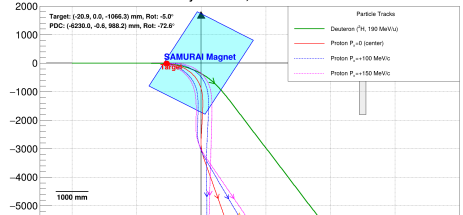
PDC Position: 5 deg (Mid Field)

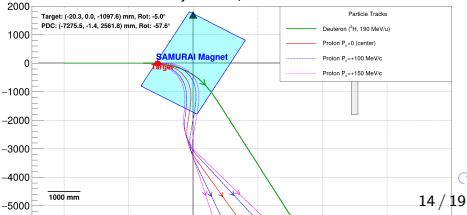


(a) 1.60 T

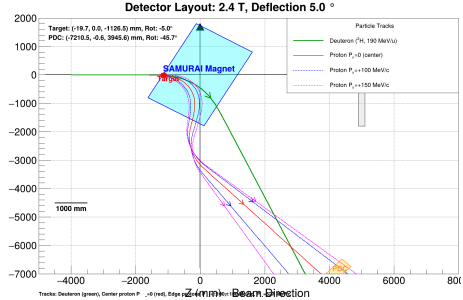


(b) 1.80 T

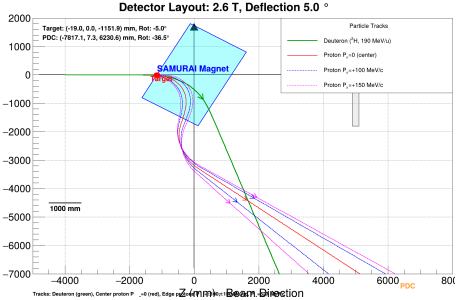




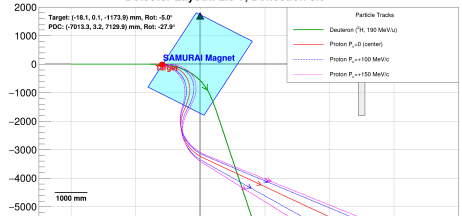
PDC Position: 5 deg (High Field)

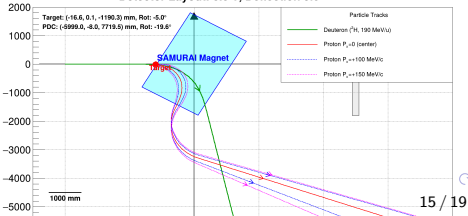


(a) 2.40 T

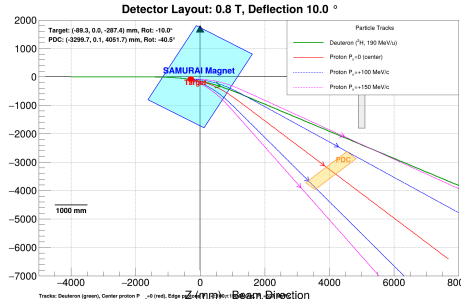


(b) 2.60 T

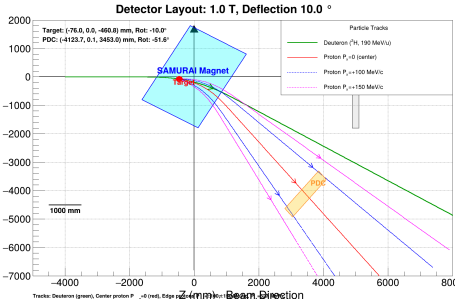




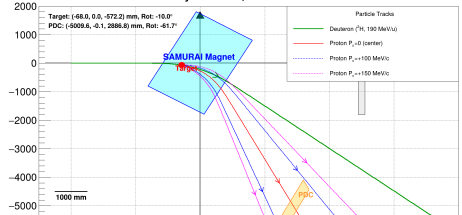
PDC Position: 10 deg (Low Field)

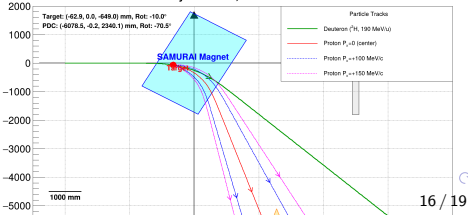


(a) 0.80 T

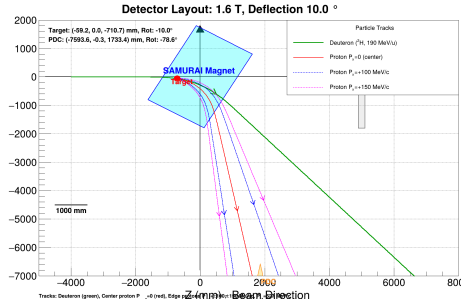


(b) 1.00 T

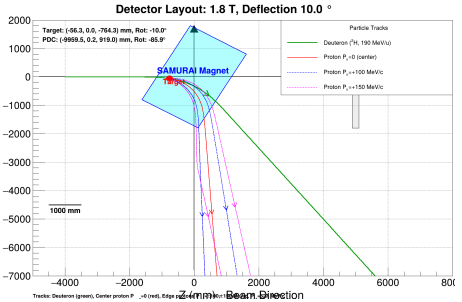




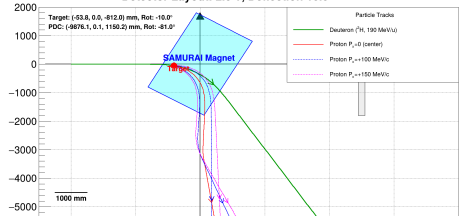
PDC Position: 10 deg (Mid Field)

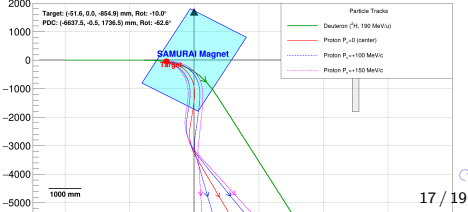


(a) 1.60 T

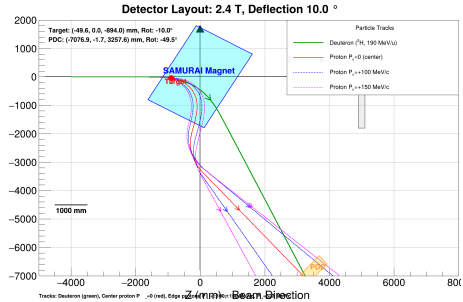


(b) 1.80 T

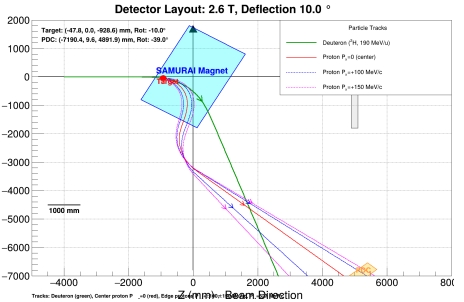




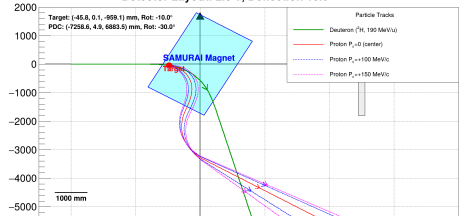
PDC Position: 10 deg (High Field)

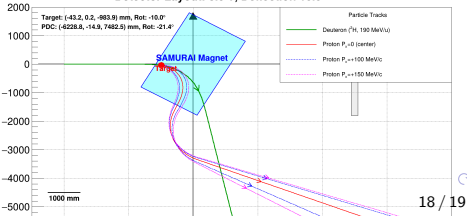


(a) 2.40 T



(b) 2.60 T





The neutron acceptance depends on the beam bending angle. Although different magnetic field settings cause slight differences in position, the impact of the magnetic field is negligible. The angle should be smaller than 10°. Furthermore, the neutron distribution does not correlate with the proton changes; for neutrons within a specific region, the corresponding protons are distributed across nearly the entire space, indicating no significant correlation. For neutrons within a specific region, the corresponding protons are distributed across nearly the entire space, indicating no significant correlation.
